

Generated-Video Content Pockets Predict Delayed Human Recognition Memory

Wave 2 Prolific old-vs-lure recognition-memory validation for the primary orange-flowers and hanging-clothes content-pocket packet.

Complete Wave 2 payloads	Primary recognition	Hard-control recognition	Paired lift
62	92.7%	80.6%	+11.7 pp

Claim Boundary

Supported: a narrow delayed old-vs-lure recognition-memory advantage for the pooled orange/hanging primary packet. Not supported: broad human memorability, measured-BMD/fMRI grounding, prompt-conditioned generation control, or general BO/SVD optimization superiority.

Important caveats: Wave 1 webhook retention was partial, although the retained overlap had zero deterministic form mismatches; the original large-sample final-confirmation plan remains stricter than this Wave 2 draft result.

Delayed Recognition Accuracy By Content Arm

Wilson 95% intervals; media-error trials excluded.

Primary Pockets Exceed Hard Controls

Participant-level paired contrast after media-error exclusion.

Pocket-Specific Lift Vs Hard Controls

The packet-level claim is stronger than the individual orange-flowers claim.

Interpretation

Hanging clothes clears the individual hard-control contrast. Orange flowers is high in absolute recognition but has a weaker standalone contrast in this Wave 2 sample. The honest claim is therefore the pooled primary packet, with pocket-specific nuance preserved.
